## ćwiczenia 35. i 36. – rozwiązania

19 i 22 stycznia 2021

1. Oblicz:

a)  $\int e^{\sqrt{x}} dx,$

Podstawiamy  $t = \sqrt{x}$ , zatem  $x = t^2$  oraz  $dx = 2t dt$ . Potem przez części

$$\int e^{\sqrt{x}} dx = 2 \int te^t dt = 2(te^t - \int e^t dt) = 2e^t(t-1) + C = 2e^{\sqrt{x}}(\sqrt{x}-1) + C.$$

b)  $\int \frac{\sqrt[6]{x} dx}{1 + \sqrt[3]{x}}.$

Podstawiamy  $t = \sqrt[6]{x}$ , więc  $\frac{dt}{dx} = \frac{1}{6\sqrt[6]{x^5}} = \frac{1}{6t^5}$

$$\begin{aligned} \int \frac{\sqrt[6]{x} dx}{1 + \sqrt[3]{x}} &= \int \frac{6t^6}{1 + t^2} dt = 6 \int (t^4 - t^2 + 1) dt - \int \frac{6dt}{1 + t^2} = \\ &= 6t^5/5 - 2t^3 + 6t - 6\arctgt + C = 6\sqrt[6]{x^5}/5 - 2\sqrt{x} + 6\sqrt[6]{x} - 6\arctg\sqrt[6]{x} + C. \end{aligned}$$

2. Oblicz:

a)  $\int \frac{2 dx}{(x-4)^4},$

$$\int \frac{2 dx}{(x-4)^4} \quad \boxed{t = x-4, \frac{dt}{dx} = 1} \quad \int \frac{2 dt}{t^4} = \frac{-2}{3t^3} + C = \frac{-2}{3(x-4)^3} + C.$$

b)  $\int \frac{dx}{x^4 + x},$

Rozkładamy mianownik na czynniki:  $(x^4 + x) = x(x+1)(x^2 - x + 1)$  i wyliczamy rozkład na ułamki proste:

$$\frac{1}{x^4 + x} = \frac{A}{x} + \frac{B}{x+1} + \frac{Cx+D}{x^2-x+1},$$

a zatem:

$$\begin{aligned} 1 &= A(x+1)(x^2-x+1) + Bx(x^2-x+1) + (Cx+D)x(x+1) = \\ &= A(x^3+1) + B(x^3-x^2+x) + C(x^3+x^2) + D(x^2+x), \end{aligned}$$

czyli:

$$\begin{cases} A = 1 \\ B + D = 0 \\ -B + C + D = 0 \\ A + B + C = 0 \end{cases}.$$

Czyli:  $A = 1, B = -\frac{1}{3}, C = -\frac{2}{3}, D = \frac{1}{3}$ , a więc:

$$\begin{aligned} \int \frac{dx}{x^4 + x} &= \int \frac{dx}{x} - \frac{1}{3} \int \frac{dx}{x+1} - \frac{1}{3} \int \frac{(2x-1)dx}{x^2-x+1} \quad \boxed{t = x^2 - x + 1, \frac{dt}{dx} = 2x-1} \\ &= \ln|x| - \frac{1}{3} \ln|x+1| - \frac{1}{3} \ln|t| + C = \ln|x| - \frac{1}{3} \ln|x+1| - \frac{1}{3} \ln(x^2 - x + 1) + C. \end{aligned}$$

$$c) \int \frac{2x+3}{(x^2+2x+4)^2} dx,$$

$x^2 + 2x + 4$  nie ma żadnych pierwiastków, więc mamy do czynienia już z ułamkiem prostym. Więc:

$$\int \frac{2x+3}{(x^2+2x+4)^2} dx = \int \frac{2x+2}{(x^2+2x+4)^2} dx + \int \frac{1}{(x^2+2x+4)^2} dx.$$

Pierwsza z tych całek to proste podstawienie, a więc:

$$\int \frac{2x+2}{(x^2+2x+4)^2} dx \quad \boxed{\begin{array}{l} t = x^2 + 2x + 4, \frac{dt}{dx} = 2x + 2 \\ \hline \end{array}} \quad \frac{-1}{x^2+2x+4} + C.$$

Z drugą całką jest więcej kłopotu, bo potrzebne jest wymyślne podstawienie  $t = \frac{x+p/2}{\sqrt{-\Delta/4}}$ , a w naszym wypadku  $\Delta = 4 - 16 = -12$  oraz  $p = 2$ , czyli  $t = \frac{x+1}{\sqrt{3}}$  i  $\frac{dt}{dx} = \frac{1}{\sqrt{3}}$ . Czyli:

$$\int \frac{1}{(x^2+2x+4)^2} dx = \int \frac{\sqrt{3} dt}{9(t^2+1)^2} = \frac{\sqrt{3}}{9} \int \frac{dt}{(t^2+1)^2},$$

i korzystamy z wzoru rekurencyjnego i dostajemy:

$$\frac{\sqrt{3}}{9} \int \frac{dt}{(t^2+1)^2} = \frac{\sqrt{3}}{18} \left( \frac{t}{1+t^2} + \int \frac{dt}{1+t^2} \right) = \frac{\sqrt{3}}{18} \left( \frac{t}{1+t^2} + \arctgt \right) + C,$$

a więc ostatecznie:

$$\int \frac{2x+3}{(x^2+2x+4)^2} dx = -\frac{1}{x^2+2x+4} + \frac{1}{6} \frac{x+1}{x^2+2x+4} + \frac{\sqrt{3}}{18} \arctg \left( \frac{x+1}{\sqrt{3}} \right) + C.$$

$$d) \int \frac{x^2-3x+2}{x(x^2+2x+1)} dx$$

Mamy:

$$\int \frac{x^2-3x+2}{x(x^2+2x+1)} dx = \int \frac{x^2+2x+1-5x+1}{x(x^2+2x+1)} dx = \int \frac{dx}{x} - \int \frac{5x-1}{x(x^2+2x+1)} dx.$$

O ile z pierwszą całką nie ma kłopotu, bo, to trzeba drugą rozłożyć na ułamki proste:

$$\frac{5x-1}{x(x^2+2x+1)} = \frac{A}{x} + \frac{Bx+C}{x^2+2x+1}.$$

A więc:

$$\begin{cases} A = -1 \\ 2A + C = 5 \\ A + B = 0 \end{cases},$$

a zatem  $A = -1, B = 1, C = 7$  i:

$$\begin{aligned} \int \frac{5x-1}{x(x^2+2x+1)} dx &= - \int \frac{dx}{x} + \int \frac{x+7}{(x+1)^2} dx = \\ &= -\ln|x| + \frac{1}{2} \int \frac{2x+2}{x^2+2x+1} dx + 6 \int \frac{dx}{(x+1)^2} = -\ln|x| + \frac{\ln(x^2+2x+1)}{2} - \frac{6}{1+x} + C. \end{aligned}$$

Zatem ostatecznie:

$$\int \frac{x^2-3x+2}{x(x^2+2x+1)} dx = \frac{\ln(x^2+2x+1)}{2} - \frac{6}{1+x} + C.$$

e)  $\int \frac{3x}{x^3 - 1} dx,$

Mamy:  $x^3 - 1 = (x - 1)(x^2 + x + 1)$ , a zatem:

$$\frac{3x}{x^3 - 1} = \frac{A}{x - 1} + \frac{Bx + C}{x^2 + x + 1},$$

czyli:

$$\begin{cases} A - C = 0 \\ A - B + C = 3 \\ A + B = 0 \end{cases},$$

zatem:  $A = 1, B = -1, C = 1$  i

$$\begin{aligned} \int \frac{3x}{x^3 - 1} dx &= \int \frac{dx}{x - 1} + \int \frac{-x + 1}{x^2 + x + 1} dx = \\ &= \ln|x - 1| - \frac{1}{2} \int \frac{2x + 1}{x^2 + x + 1} dx + \frac{3}{2} \int \frac{dx}{x^2 + x + 1} = \ln|x - 1| - \frac{\ln(x^2 + x + 1)}{2} + \frac{3}{2} \int \frac{dx}{x^2 + x + 1}, \end{aligned}$$

a w przypadku tej ostatniej całki potrzebujemy naszego podstawienia:  $t = \frac{x+p/2}{\sqrt{-\Delta/4}}$ , a w naszym wypadku  $\Delta = 1 - 4 = -3$  oraz  $p = 1$ , czyli  $t = \frac{2x+1}{\sqrt{3}}$  i  $\frac{dt}{dx} = \frac{2}{\sqrt{3}}$ . Czyli:

$$\int \frac{dx}{x^2 + x + 1} = \int \frac{\sqrt{3}/2}{\frac{3}{4}(t^2 + 1)} dt = \frac{2\sqrt{3}}{3} \operatorname{arctgt} = \frac{2\sqrt{3}}{3} \operatorname{arctg} \frac{2x+1}{\sqrt{3}} + C,$$

a zatem w końcu:

$$\begin{aligned} \int \frac{3x}{x^3 - 1} dx &= \\ &= \ln|x - 1| - \frac{\ln(x^2 + x + 1)}{2} + \frac{3}{2} \frac{2\sqrt{3}}{3} \operatorname{arctg} \frac{2x+1}{\sqrt{3}} + C. \end{aligned}$$

3. Oblicz:

a)  $\int \frac{x + \sqrt{2x - 3}}{x - 1} dx.$

$$\begin{aligned} \int \frac{x + \sqrt{2x - 3}}{x - 1} dx &\quad \boxed{t = \sqrt{2x - 3}, x = \frac{t^2 + 3}{2}, \frac{dt}{dx} = 1/\sqrt{2x - 3}} \\ &= \int \frac{t^3 + 2t^2 + 3t}{t^2 + 1} dt = \int \left( t + 2 + \frac{2t}{t^2 + 1} - \frac{2}{t^2 + 1} \right) dt = \frac{t^2}{2} + 2t + \ln(t^2 + 1) - 2\operatorname{arctgt} + C = \\ &= \frac{2x - 3}{2} + 2\sqrt{2x - 3} + \ln(2x - 2) - 2\operatorname{arctg}\sqrt{2x - 3} + C. \end{aligned}$$

b)  $\int \frac{dx}{e^x + e^{-x}},$

$$\int \frac{dx}{e^x + e^{-x}} \quad \boxed{t = e^x, \frac{dt}{dx} = e^x} \quad \int \frac{dt}{t(t + t^{-1})} = \int \frac{dt}{t^2 + 1} = \operatorname{arctgt} + C = \operatorname{arctg} e^x + C.$$

c)  $\int \frac{dx}{3 \sin x + \cos x}.$

$$\begin{aligned} \int \frac{dx}{3 \sin x + \cos x} &\quad \boxed{t = \operatorname{tg} \frac{x}{2}, \frac{dt}{dx} = \frac{1 + \operatorname{tg}^2 \frac{x}{2}}{2}, \sin x = \frac{2t}{1 + t^2}, \cos x = \frac{1 - t^2}{1 + t^2}} \\ &= \int \frac{\frac{2}{1+t^2} dt}{\frac{1}{1+t^2}(6t + 1 - t^2)} = \int \frac{2 dt}{-t^2 + 6t + 1} = \int \frac{dt}{t - 3 - \sqrt{10}} - \int \frac{dt}{t - 3 + \sqrt{10}} = \ln|t - 3 - \sqrt{10}| - \ln|t - 3 + \sqrt{10}| + C = \\ &= \ln \left| \operatorname{tg} \frac{x}{2} - 3 - \sqrt{10} \right| - \ln \left| \operatorname{tg} \frac{x}{2} - 3 + \sqrt{10} \right| + C. \end{aligned}$$
